

hfill in LaTeX is a horizontal fill command that expands to create a stretchable space between elements on the same line. It pushes the subsequent content as far as possible to the right within the available space. Here are some examples:

Some text More text Even more text.

Here, `hfill` adds stretchable space between “Some text,” “More text,” and “Even more text,” pushing them to the left and right margins.

Left-aligned text Center-aligned text Right-aligned text

Here, `hfill` is used to align the content to both the left and right margins. The center-aligned text will be positioned at the center of the available space.
